ABSTRACT

World Wide Web authors are often tempted to use the latest and sexiest means to present their information. "Hot" and "cool" sites use dancing graphics, frames, tables, specific fonts, and background and foreground colors to entice the reader and delight the eye. Sound clips often convey emotional content that cannot be expressed in text, and digital video clips present movement. However, the use of these means tends to disenfranchise some users. It is important to consider potential users' limitations, and make information accessible to all. Deaf readers need text support for sound clips, as well as visual clues to any audio stimuli, including beeps and bells. Blind readers need to be able to access the information content through text presented in a linear manner, so that it can be rendered as sound through their specialized equipment. Readers at the end of a telephone line need access to the information content even when they turn off the display of online images, and readers with older computers need pages that work with a text browser, such as Lynx. This paper describes hypertext markup language (HTML) coding techniques to enhance accessibility without totally forsaking attractiveness. The paper is intended for Web authors who can understand HTML tagging without lengthy explanations. (Contains 15 references.) (Author/SWC)

Abstract.

Web authors are often tempted to use the latest and sexiest means to present their information. "Hot" and "Cool" sites use dancing graphics, frames, tables, specific fonts, background and foreground colors to entice the reader and delight the eye. Sound clips often convey emotional content that cannot be expressed in text. Digital video clips are jerky but they do move.

This tends to disenfranchise some users, however. When we put up web pages to provide information to our clientele, we need to remember their limitations, and make our information accessible. Deaf readers need text support for sound clips, as well as visual clues to any audio stimuli, including beeps and bells. Blind readers need to be able to access the information content through text presented in a linear manner, so that it can be rendered as sound by their specialized equipment. Readers at the end of a telephone line need access to the information content even when they turn off display of inline images, and readers with older computers need pages that work with a text browser, such as Lynx.

The presentation will demonstrate HTML coding techniques to enhance accessibility without totally forsaking attractiveness. The potential audience will be web authors who can understand HTML tagging without lengthy explanations.

Audience.

Writing HTML for accessibility differs according to the needs of the audience. While many of my suggestions are applicable across the board, there are some considerations that apply particularly to specific groups of users.

Blind readers.

The usual coping mechanism for blind readers of computer screens is to use a screen reader program to render the text of the screen as speech with a speech synthesizer or in Braille with a refreshable Braille display. (Paciello) The speech synthesizer may be standalone hardware, such as DecTalk, or software used in connection with a standard sound card, such as TextAssist, which comes bundled with SoundBlaster cards from Creative Labs.

Screen readers do a pretty amazing job of translating the characters on a screen, reading from left to right and top to bottom, into phonemes which are spoken by the hardware. Most screen readers take total control of the hardware, however, and override the possibility of playing embedded sound files through the sound card. A specialized web page reader, [pwWebSpeak](#), overcomes this limitation. Pages designed to be taken in at a glance, using colors and type sizes to draw the eye to particular parts, take on a whole new "look" when read aloud serially.

Deaf readers.

Web pages are mostly accessible to deaf readers. Audio clips are an obviously inaccessible element. Some of the sound cues provided by web pages and web browsers should be reinforced with visual cues. Windows 95 has accessibility options, including SoundSentry and ShowSounds to accommodate deaf users. SoundSentry is available for Windows 3.1 as part of the Access Pack at <http://www.windows.com/windows/enable/accessw.htm> by mail or FTP.

Many hearing readers have non-speaking computers (no sound cards). Both deaf readers and these impoverished souls (including most users of Library computers) are helped by web authors who include a text alternative, or at least a description, for each audio clip.

Poor readers.

Not everyone can have the latest Intel and Microsoft wallet-shrinking toys. Many of our readers make do with slow modems, and turn off automatic loading of images. Freenets and low-end Internet service providers supply UNIX shell access to the WWW with Lynx text-only browsers. Most third world access to the Web is through such narrow pipes.

Webmasters who count access by browser type cite low percentages of Lynx users as justification for using the more resource intensive HTML features. This smacks of the self-fulfilling prophecy; who would visit www.sears.com a second time with Lynx or with images turned off? In a recent exchange on the web-consultants discussion list, Gregory J. Rosmaita, under the pseudonym Oedipus wrecked, suggests that the number of non-graphic browser users is understated:

even a cursory glance at the lynx-dev mailing list's hypertext archives would reveal that, currently, there are Japanese, Chinese, Egyptian, Turkish, Brazilian, American, Canadian, German, Swedish, Ukranian, Russian, and a host of other programmers working on national charsets, libraries, and patches for lynx... if lynx's user base was as small as is claimed on this list, it would have breathed its last with the release of 2.4.2 (Gill, The Web: Design,

ADA and Lynx)

Practicalities.

This section will present specific suggestions for improving HTML with an eye to accessibility by all the audiences explored above.

Compatibility.

What works in Lynx will work in all other browsers; the converse is not true. Designing for Lynx requires clean HTML 2.0 code; providing alternatives for blind and deaf users also accommodates readers without disabilities who have diverse learning styles. For example, a .jpg image of a medieval manuscript is visually impressive, but inaccessible to a blind reader. Provision of a transcribed text not only allows the blind reader access to the content on one level but also provides the sighted reader with a key to deciphering the text, which is likely to be full of medieval abbreviations.

Many Web authors do not know the differences among the HTML standards, and may not realize how badly the pages they write with WYSIWYG editors may present themselves in diverse browsers. Gerald Oskoboiny does us all a great service with his "Kinder, Gentler Validator" at <http://ugweb.cs.ualberta.ca/~gerald/validate/> where he offers HTML grammar checking and Weblint style analysis. If you submit a page without a `<!DOCTYPE>` declaration it will be parsed at HTML 2.0 level and the information that Gerald makes available will teach you much about the various flavors of HTML.

Oskoboiny also provides a way to see approximately how your pages would appear in Lynx without launching a Lynx browser. <http://ugweb.cs.ualberta.ca/~gerald/lynx-me.cgi> is the address; this is actually a script that requires a URL as an argument, but try the address given to get further instructions from Gerald directly.

Images.

No `` tag should be published to the world without the `alt=""` parameter. (Fontaine) For images that contribute content to the document, provide a concise description, preferably within square brackets, since Lynx users associate square brackets with images, usually in the useless form `[image]` or `[inline]`. For example `` would alert the user that there is a picture of Paul available. Inclusion of the width and height attributes does nothing for the Lynx user, but does save the time of the graphic browser user, since the browser can reserve a space 44 by 60 pixels and continue to display text without having to stop and retrieve the image from the server to take its measurements.

Text expressed not in ASCII characters but as part of an image, often in a banner or letterhead image, must be expressed in `alt="the words in the image"` to avoid losing content without the image.

Larger images should be presented in thumbnail versions, with a link to their larger selves to be loaded on demand. The link text would include the thumbnail image itself and an indication of its approximate size in kilobytes, as in this example: ` 47K The full-size image will be loaded as a separate page if the link is selected by the user. Since it stands alone, no provision for including its width and height is needed.

An image editor, such as LviewPro or Photoshop, can easily create smaller versions of .gif or .jpg images for use as thumbnails. It is also possible to use the same file for both, with the width and height attributes used to tell the browser to reduce the image size on the fly, but this means asking the user to do with each load work that can be done once only. This is a blatant violation of Ranganathan's fourth law of library science, "Save the time of the Reader."

Images that are purely decorative, contributing to the look of the graphic page but useless to the non-graphic browser user, can be hidden from the latter's sight or hearing by using the alt= parameter to make the alternative text a null or empty string: `` Note that there is absolutely nothing between the quotes.

Image Maps.

Graphic designers love them, HTML writers are pleased as punch to make them work at last, but ISMAP images are absolutely useless to readers without graphics. For these users we need to provide either a link to a text-based alternate page or a set of text links in the page with the map itself. My preference is for the latter approach, with the image map carrying a null string as alternative text, lest a user select it as a link without any coordinates. (Fontaine)

Buttons.

Some page designers seem to resent the conventional look of link text in bright blue with underlining, preferring to use buttons as link images. They often add the border=0 parameter to the `` tag to prevent the blue border that indicates a link. When they provide alternate text for the buttons it is likely to be alt="*" which creates a bit of a mystery for the Lynx user reading the page with a screen reader and a voice synthesizer. These pages can also be mysterious to sighted users with graphic browsers, unless they are savvy enough to notice that the cursor changes shape when poised over a link image.

My preference is to use link text in association with images that suggest the target, if appropriate. I welcome the blue border and the bright blue underlined text convention that gives the user belt-and-suspenders assurance that this is indeed a link.

"Click here".

One way to avoid the "click here" syndrome, is to test pages in Lynx, which does not click at all. Link text should express concisely what the user will reach by selecting the link. A list of link text items should sound like an invitation to content, not a litany of "here, here, this, here, this, here" and "click me." (Fontaine)

Audio.

Links to audio clips should be accompanied by alternative links to text of an

announcement, lyrics of a song, or a description of the sounds that would be heard if the user could hear them. For example, it would be delightful if The Capitol Steps (<http://www.capsteps.com/>) would provide a link to the script for *Lirty Dies: Graberdeen Grooving Pounds* as well as links to the .au and RealAudio formats of the monologue.

Linking to a site that automatically starts playing a tune can be quite disconcerting on a browser that cannot play the tune; an error message is likely to pop up in the user's face. One such is the satiric <http://www.highersource.org/> site (not to be confused with the .com site), which plays the theme from M*A*S*H ("Suicide is Painless") as background.

Other formats.

Just as it is helpful to provide a text alternative to an audio clip, providing either a text or an HTML alternative to a .pdf file is a lifesaver to readers who cannot see or display these Adobe Acrobat pages. (Fontaine)

Not all browsers can handle forms. If you are really concerned about giving the reader a means to provide information to you or your organization, provide alternatives. Many sites give users a choice among:

- an online form;
- a text form that can be downloaded, filled in, and returned by e-mail or snail mail;
- or
- a telephone number to call.

While it is beyond the scope of this paper, when possible moving pictures may be made accessible by adding captions in text or in ASL and by providing a descriptive soundtrack for blind users. If such options are available, they should probably be provided in side-by-side alternative links, rather than included in the only copy of the movie provided. (Vanderheiden)

Lists.

Lists are pretty straightforward HTML elements, but there are a couple of hints that will improve accessibility of lists:

- if using graphics as bullets, provide alt="*" or alt="o" parameters in the tag.
- include closing punctuation on list items, even if the items are not grammatical sentences, for the benefit of users with screen readers rendering either speech or Braille.

Closing punctuation (full stop or period) is nearly invisible in lists, but looks a little silly on headings, but it makes a big difference in how the headings sound with a screen reader. Did you really notice the periods in the headings in this page?

I also added a
 tag at the end of almost every URL that was expressed as such in the text. This really helps clarify to the hearer that the end of the link has been reached, especially when the speech synthesizer tries to interpret and pronounce the "words" in the URL; for example, the synthesizer reads the "ca" in ugweb.cs.ualberta.ca as "California."

Tables.

From an accessibility standpoint, concern for users with screen readers suggests a "just say no" policy. Screen readers read the screen line by line, an approach which creates chaos when it encounters even a relatively simple table or columnar arrangement of data. Try reading the following table in a line-by-line fashion:

Table type	Results in Lynx	Screen reader results
preformatted text in columns and rows	spacing of the original text is preserved in fixed spacing typeface	line-by-line reading does violence to the logic of the text arrangement
<table>standard table construction</table>	all table-related tags are ignored, text is presented in a blob, line by line ignoring line ends	same as above
standard table construction with tags at end of each cell	table-related tags are ignored, but tags cause new line starts; significance of headings is lost	if screen reader is reading Lynx screen, new line indicates new topic, but logic of columns may not be obvious

An appropriate use of preformatted text may be seen in my personal home page at <http://www.csun.edu/~mreagan/> where I include the .sig block that I use in electronic mail as a concise way to display address and telephone numbers. It is a two-column presentation that does not lose too much when read line by line:

pager (818) 828-1226		packet KK6WO@W6VIO.#SOCA.CA.USA.
----- de gustibus non est disputandum -- --		

The roster of the CSU, Northridge Faculty Executive Committee is an example of the use of table logic with
 tags to make it work in Lynx. Its URL is <http://www.csun.edu/~fs20469/execom.html> and it has an extra
 tag in the right-hand cells to create vertical white space between entries when displayed in Lynx.

Frames.

Like many of the participants in the web4lib discussion list, I have seen few examples of the use of frames that justify the grief this feature causes to the disenfranchised user. Lynx cannot handle frames, screen readers balk at them, older browsers stop in their tracks.

If you do feel a need to use frames logic, create the page without it as well, and include a link at the top of the frames page to let your readers get to the non-frames version. Do this for every page on which you use frames. If you are within the range of normally lazy humanity, you will stop putting yourself through the agony of writing the frames version.

If your WYSIWYG HTML tool insists on writing with frames, throw it out.

Applets.

The arguments above about frames apply in spades to Java applets. They are potentially quite powerful, but address only the "rich, well-born, and able" browsers running in 32-bit operating systems. The World-Wide Web is still predominantly a 16-bit world, with huge installed bases of Windows 3.1 machines. Java makes perfect sense if you are selling a product to Sharper Image customers, or if you are addressing an Intranet running only Windows 95 or Windows NT or PowerPC Macintosh machines.

Microsoft ActiveX has most of the same disadvantages as Java plus a reputation for creating security problems that has many users refusing to allow it.

Limited video.

Be kind to your less well-endowed readers when including images in web pages. Some of us have video cards with extremely limited memory, so the precise shade of off-mauve that best sets off your page featuring a true-color photograph of your award-winning black and white Dalmatian is likely to show up as a deadly drab dithered dot design. Limiting backgrounds to standard colors, and images to a small palette will produce more uniform results across the user base.

My graphic editor is the freeware LviewPro. When I open an image file the upper border displays the file name and its three dimensions, width in pixels, height in pixels, and number of colors in the palette used. It is amazing how much difference can be made in the size of the image file by reducing the number of colors used. A scanned image of a postcard printed on a wood-grain background was 62,151 bytes in .jpg format. As seen in an experiment with LviewPro at <http://www.csun.edu/~mreagan/images.html> the size was reduced to 30,569 bytes by limiting the number of colors, and further reduced to 18,345 bytes by saving it in .gif format. Choosing a reduced file size, if the image quality is still adequate, "Saves the time of the Reader."

Smaller image sizes help keep the total page size within reason. Pages larger than 50K to 75K total should be scrutinized carefully. Many readers will hit the stop button rather than wait to see large pages. (Gill, Issues)

<Blink>.

Don't.

Many users are annoyed by blinking text and animated .gif images, but a few could be injured by them. Some epileptic seizures are triggered by pulsing light. Blinking text is pulsing light. Need I complete the syllogism?

Screen readers used to translate text into speech or Braille are usually stymied by blinking text, making it impossible for the user to read the rest of the screen.

Just don't.

Futures.

A simple change of habit will help avoid a "Y2K" problem on web pages. What date is 01/02/03 on the World-Wide Web? Taking the time to write January 2, 2003, 1 February 2003, or 3 February 2001 will avoid confusion. (Starling)

Screen readers of the future, optimized for HTML, are likely to do a better job of expressing , , <cite>, or <var> than or <i>. (DO-IT)

A Homily.

As if I haven't been preaching throughout this paper

Appearances.

Much effort is successfully employed in creating printed advertising with the most appropriate type faces in exactly the right sizes, custom artwork rendered just so, perfectly placed illustrative material, and all the tools of subliminal seduction marshaled to engage the intended audience. The obvious potential of the World-Wide Web has tempted many to bring their advertising toolbox to this new medium. Some Web authors have gone to great lengths in their attempts to control presentation, even including tailored quantities of invisible single-pixel .gif images to force the spacing of text on a web page.

Yet, HTML is a Markup Language. It is designed to separate content from specific presentation of information. It expects the designer to indicate sentences, paragraphs, etc. in a simple way to format clear text. Yet many page designers, in an effort to create a "magazine on the screen," have resorted to clever techniques to extend the range of HTML. They endeavor to force the browser to "display" that information in a specific way--a method which may exactly match the format which the designer might pick if he/she had complete control. (Murphy)

This effort is doomed to failure, because the balance of power in the Web is shifted away from the page producer. The look and feel of a web page is determined by three elements:

1. The internal logic of the browser client software has primary control. Pages will look different on PCs and on Macintoshes. Netscape, Mosaic, and Internet Explorer all have different approaches to display, both among themselves and between their own versions. Lynx obviously does things differently.
2. The browser options selected by the user are secondary but powerful. Whether as a matter of taste or as a matter of necessity, users are likely to choose different base typefaces and font sizes, monitor resolutions, and background colors, and make such basic decisions as whether to allow loading of images or to override page preferences with their own.
3. The choices coded by the Web author are tertiary.

Since control of the output is futile, you can afford to make your pages as widely accessible as possible and embrace the

KISS principle (keep it simple, stupid).

- Focus on content.
- Use tagging that makes the content clear to the widest possible audience.
- Embrace the conventional - bright blue underlined text is unmistakably a link.
- Use "sexy" features, bells and whistles only if delivery of the content requires them and limited accessibility is acceptable.

Allow exceptions.

Not every page can be usable in Lynx. The images.html page referenced above is readable in Lynx, but the essential information simply cannot be conveyed without graphic capabilities. A page on leitmotifs in Mozart is likely to require audio clips and .pdf scores. The reference desk schedule at CSU, Northridge is much clearer and easier to maintain in <table> format, and its limited audience is all adequately equipped to handle tables. Life writing web pages with an accent to access need not be drab.
